

Customer & Orders Database:

- I made a simple SQL database with Customers and Orders tables.
- Customers has CustomerID, CustomerName, and City.
- Orders has OrderID, CustomerID, Product, Amount, and OrderDate.
- CustomerID in Orders links to Customers so the data stays connected.
- I also created a view called OrderSummary to quickly see which customer bought what, and an index on City in Customers to make searching faster.

Some of the things I did with this database:

- Found all customers in Chennai and sorted them by name.
- Counted how many customers are in each city.
- Calculated how much each customer spent in total and on average.
- Used INNER JOIN and LEFT JOIN to combine customer and order info.
- Checked which customers bought expensive stuff (over 10,000).
- Used the OrderSummary view to see customer orders quickly.
- Checked the index to see optimization.

Basically, I created the tables, added some data, made a view and index, and then ran different queries to test and analyze the data.
